

Evidences for evolution

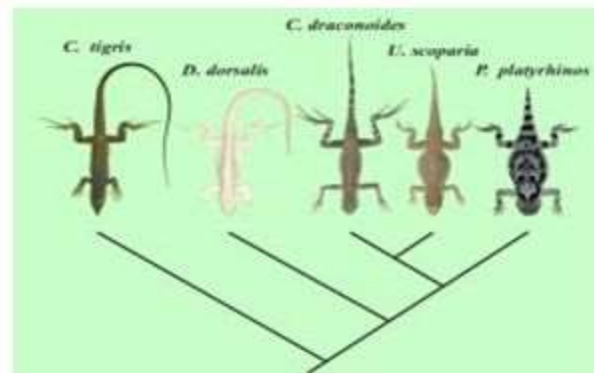

Evidences of Evolution

- 1. Biogeography**
- 2. Fossils**
- 3. Taxonomy**
- 4. Comparative Anatomy**
- 5. Comparative Embryology**
- 6. Molecular Biology**

- To trace **phylogeny** (the evolutionary history of life) biologists use evidence from paleontology, molecular data, comparative anatomy, etc.
 - Tracing phylogeny is one of the main goals of **systematics**, (the study of biological diversity in an evolutionary context.)
 - Systematics includes taxonomy, which is the naming and classification of species and groups of species.

As Darwin correctly predicted, “our classifications will come to be, as far as they can be so made, genealogies.”

Evidence from comparative anatomy

Evidence supporting theory of evolution

- **Analogous structures**
 - Structures similar in form and function.
- Develop as a result of convergent evolution?

Comparison of analogous structures

insect (ant) leg

fish (sculpin) fin

insect
(cicada)
wing

horse leg

dolphin flipper

bird (chicken) wing

Vestigial Structures

- **Vestigial Structures:** characteristics found in existing species that have **no known function**
- Provide **evidence of common ancestry**
- As species evolve their structures change
 - Two things will happen
 - Species will adapt the organ/structure to a new use
 - penguin
 - The organ or structure will no longer have a use
 - Whale pelvis/snake feet.

4. Vestigial organs

- remains of structures/organs that ONCE had an importance in organism's ancestors
 - Example: tailbones in humans, appendix, wings on ostrich, wisdom teeth in humans, nipples in male mammals, femur and pelvis in whales

Comparative Anatomy

Vestigial structures are body parts that have lost their original function through evolution.

Between 50–40 million years ago, this mammal breathed air and walked clumsily on land. It spent a lot of time in water, but swimming was difficult because of its rear legs. Individuals born with variations that made their rear legs smaller lived longer and reproduced more. This mammal is an ancestor of modern whales.

Ambulocetus natans

Modern toothed whale

After 10–15 million more years of evolution, the ancestors of modern whales could not walk on land. They were adapted to an aquatic environment. Modern whales have two small vestigial pelvic bones that no longer support legs.

Tail bone in human being

Nictitating membrane in the eyes of man (Left) and ape (Right)

Vestigial auricular muscles of the pinna in man

Vestigial caecum and vermiform appendix in man

4) ATAVISM OR REVERSION

- Definition: It involves the reappearance or refunctioning of those organs which are either completely lost, or are present as vestigial organs.
- Such characters indicate the ancestral history
- Example: Birth of a human baby with a small tail, development of power of moving pinna in some person
- Significance: It support organic evolution that living organism have ability to develop even lost or non-functional structures.

Some human atavistic characters. A—Human baby with tail, B, C—Cervical fistula or rudimentary gill-slits, D—Additional nipples, E—Pointed canine tooth, F—Thick hair on body.

Adaptive Radiation

1. Type of divergent evolution
2. One species or group evolved through natural selection into many diverse forms

3. Examples:

- Darwin's finches
- Mammals after dinosaur extinctions

bat (flying)

The **pentadactyl limb** as the 'ancestral' terrestrial vertebrates limb plan, subsequently adapted by modification for different uses/habitats.

lay-out of a 'five-fingered' (pentadactyl) limb

monkey (grasping)

forelimb

hindlimb

upper arm → humerus

femur ← thigh

forearm → radius + ulna

tibia + fibula ← lower leg

wrist → carpals

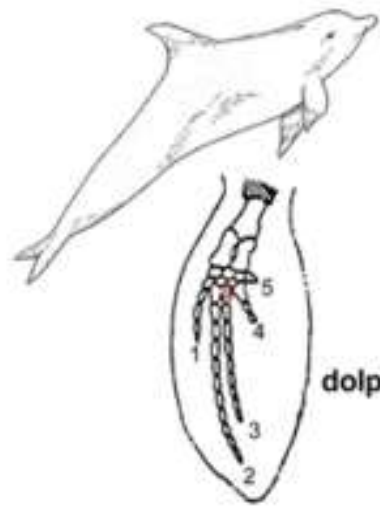

tarsals ← ankle

hand/foot → metacarpals + phalanges

metatarsals ← foot + phalanges

digits

dolphin (swimming)

pig (walking)

anteater (tearing)

mole (digging)

horse (running)

Evidence from connecting links

Evidences from evolutionary link

<i>organism</i>	<i>Connecting link</i>
<i>virus</i>	<i>Living & non living</i>
<i>euglena</i>	<i>Plants & animals.</i>
<i>Peripatus</i>	<i>Annelida & arthropoda</i>
<i>Neopilina</i>	<i>Annelida & mollusca</i>
<i>Dipnoi (lung fish)</i>	<i>Pisces & amphibia</i>
<i>Archaeopteryx</i>	<i>Reptiles & aves</i>
<i>Protothera</i>	<i>Reptiles and mammals</i>

A. Palaeontological Evidence

Palaeontology deals with study of fossils. Fossils are described as true witnesses or documents of evolution. Fossil record provide the connecting link between two groups of organisms. e.g. *Archaeopteryx* is a connecting link between reptiles and birds.

Evidence from embryology

Embryology

- Embryology is a new method of examining evidence of evolution
 - Embryo = first 9 weeks of vertebrate development
- Embryonic structures of different species show significant similarities
- By studying the same patterns of early development across many different animals, we can find evolutionary links between animals

Evidence from molecular record

Molecular record

- Comparing DNA & protein structure
 - compare common genes
 - cytochrome C (respiration)
 - hemoglobin (gas exchange)
 - Closely related species have sequences that are more similar than distantly related species
